The Euler approach for computing $Z^w/_{knots}$ is way-over-computable.

* Is there a "universal" computation
* Can one "parametrize" all computations?

What does Polyak refer to when he says that [GPV] contains a universal FT invariant of virtual knots?

Wagner's exercise: Understand the relationship between mutation, pA and uA.
Does mutation follows from overcrossings commute and commutators commute?

Q Is there a graph-theory level perspective of the Alexander polynomial as a Reid. torsion? (meaning, using only C_1 & C_0, and the knot may as well be virtual).
