A POLY-TIME KNOT POLYNOMIAL VIA SOLVABLE APPROXIMATION

DROR BAR-NATAN AND ROLAND VAN DER VEEN

ABSTRACT. We construct the first poly-time-computable knot polynomial since Alexander's [Al, 1928] by using some new commutator-calculus techniques and a Lie algebra \mathfrak{g}_1 which is at the same time solvable and an approximation of the simple Lie algebra sl_2 .

1. INTRODUCTION

An excellent classical paper in mathematics would state a great theorem in the first couple pages of the introduction, describe its significance in section 2, and then present its proof in the remaining sections. We cannot match that; as a "theorem", our result is that a certain algorithm works well. We cannot even state the theorem without describing the algorithm, and a wordy description of the algorithm would either be lengthy and unmotivated, or would take up a whole paper. So instead of a wordy description we provide a complete implementation, right below in Figure 1.1, along with one usage example. Once it is established that the algorithm fits in less than a page of code, we move on to explain why we think it is valuable, and more importantly, how it arises from a traditional construction applied to a non-traditional Lie algebra which enables a non-traditional computational technique.

Theorem 1.1. The program in Figure $\stackrel{\text{fig:Splash}}{1.1 \text{ computes } z_1}$, a polynomial invariant of knots, in time polynomial in the crossing number.

fig:Splash

The invariant z_1 is in fact quite strong — explicit computations show that it separates more knots in the standard knot tables than the Alexander polynomial, the Jones polynomial, the HOMFLY-PT polynomial, and Khovanov homology (even when these are combined)! See the table in Section 5.

This is exciting news. The main reason is self-evident — z_1 is the first poly-time computable polynomial invariants of knots since the Alexander polynomial, discovered nearly 90 years ago [Al, 1928]. A further reason is explained in Section 6 — it seems that z_1 has a

3

A POLY-TIME KNOT POLYNOMIAL VIA SOLVABLE APPROXIMATION

better chance than anything else we know to detect potential counterexamples to the ribbonslice conjecture. Finally, z_1 is founded on some new Lie-theoretic techniques, it seems to be possible to generalize it in several directions, and many questions are raised. See Section 7.

Our z_1 can be considered as a perturbation of another invariant, z_0 , which is somewhat weaker yet in many ways it is more valuable. It is computed by a shorter program (see Figure 3.1) which runs faster, and it has a proven topological significance. The main reason z_0 is not the main character of this paper is that it is already well known: restricted to knots z_0 is the Alexander polynomial and considered on pure tangles (see Section 3) it is equivalent to the " β -calculus" of [BNS, BN2], which in itself is mostly equivalent [Ha] to Archibald's calculus [Ar] and is a mild extension of the Burau-Gassner theory of [LD, KLW, CT, CC].

As we shall see in Section $4, z_1$ arises from a certain Lie algebra \mathfrak{g}_1 , and as we shall see in Section $3, z_0$ arises from a certain Lie algebra \mathfrak{g}_0 . Within this introduction we only wish to define these two Lie algebras and explain how they arise as "(solvable) approximations of sl_2 ".

Definition 1.2. Over the field \mathbb{Q} of rational numbers, let \mathfrak{g}_0 be the 4-dimensional Lie algebra generated by elements b, c, u, and w, such that b is central, [c, u] = u, [c, w] = -w, and [u, w] = b:

$$\mathfrak{g}_0 := \mathbb{Q}\langle b, c, u, w \rangle / ([b, -] = 0, [c, u] = u, [c, w] = -w, [u, w] = b)$$
.

We grade \mathfrak{g}_0 by declaring that $\deg(b, c, u, w) = (1, 0, 1, 0)$.

Note that \mathfrak{g}_0 is solvable: Indeed

$$\mathfrak{g}_0 \supset \langle b, u, w \rangle \supset \langle b \rangle \supset \{0\}$$

is a tower of ideals of \mathfrak{g}_0 whose consequetive quotients are Abelian.

Definition 1.3. Over the ring $R := \mathbb{Q}[\epsilon]/(\epsilon^2 = 0)$, let \mathfrak{g}_1 be the 4-dimensional Lie algebra generated by elements b, c, u, and w, such that b is central, [c, u] = u, [c, w] = -w, and $[u, w] = b - 2\epsilon c$:

$$\mathfrak{g}_1 := R\langle b, c, u, w \rangle / ([b, -] = 0, [c, u] = u, [c, w] = -w, [u, w] = b - 2\epsilon c)$$
.

We grade R and \mathfrak{g}_1 by declaring that $\deg(b, c, u, w, \epsilon) = (1, 0, 1, 0, 1)$.

Note that over \mathbb{Q} , \mathfrak{g}_1 is an 8-dimensional solvable Lie algebra: Indeed

$$\mathfrak{g}_1 \supset \langle b, u, w, \epsilon b, \epsilon c, \epsilon u, \epsilon w \rangle \supset \langle b, \epsilon b, \epsilon c, \epsilon u, \epsilon w \rangle \supset 0$$

is a tower of ideals of $\mathfrak{g}_1/\mathbb{Q}$ whose consequetive quotients are Abelian.

For the purposes of this paper, we do not need to know that \mathfrak{g}_0 and \mathfrak{g}_1 are related to the classical Lie algebra sl_2 , and hence the next few paragraphs¹ can safely be skipped. Yet these paragraphs say that "there's more where \mathfrak{g}_0 and \mathfrak{g}_1 came from", and strongly suggest that there's more where our z_0 and z_1 come from.

Let \mathfrak{g} be an arbitrary semi-simple Lie algebra over \mathbb{Q} , and let $\mathfrak{g} = \mathfrak{n}^+ \oplus \mathfrak{h} \oplus \mathfrak{n}^-$ be MORE.
