Given a fixed linking matrix  $A$ , let  $\mathcal{D}^{ns}$  be the stratless part of  $\mathcal{D}$ . It is graded by the total degree  $m$  and by the log-count  $2l$ :

$$\mathcal{D}^{ns} = \bigoplus_{m,l} \mathcal{D}_{m,l}^{ns} \quad \left( \text{E.g. } \begin{array}{l} \text{has } m=5 \\ 2l=4 \\ l=2 \end{array} \right)$$

$$\text{Then } \hat{A}_1 : \mathcal{D}_{m,l}^{ns} \longrightarrow \mathcal{A}(\mathcal{D})_{m-l}.$$

Question. Is there a global meaning to the grading of  $\mathcal{D}^{ns}$  by  $(m-l)$ ?

Question. Is there a local Gaussner-style "bracelet theory"?
