

Meta-Groups, Meta-Bicrossed-Products, and the Alexander Polynomial, 1

Abstract. A straightforward proposal for a group-theoretic invariant of knots fails if one really means groups, but works once generalized to meta-groups (to be defined). We will construct one complicated but elementary meta-group as a meta-bicrossed-product (to be defined), and explain how the resulting invariant is a not-yet-understood generalization of the Alexander polynomial, while at the same time being a specialization of a somewhat-understood “universal finite type invariant of w-knots” and of an elusive “universal finite type invariant of v-knots”.

Bicrossed Products. If $G = HT$ is a group presented as a product of two of its subgroups, with $H \cap T = \{e\}$, then also $G = TH$ and G is determined by H, T , and the “swap” map $sw^{th} : (t, h) \mapsto (h', t')$ defined by $th = h't'$. The map sw satisfies (1) and (2) below; conversely, if $sw : T \times H \rightarrow H \times T$ satisfies (1) and (2) (+ lesser conditions), then (3) defines a group structure on $H \times T$, the “bicrossed product”.

$tm_1^{12} // sw_{14} = sw_{24} // sw_{14} // tm_1^{12}$ $hm_3^{12} := sw_{12} // tm_1^{12} // hm_3^{12}$

A **Meta-Bicrossed-Product** is a collection of sets $\beta(H, T)$ and operations tm_z^{xy}, hm_z^{xy} and sw_z^{th} (and lesser ones), such that tm and hm are “associative” and (1) and (2) hold (+ lesser conditions). A meta-bicrossed-product defines a meta-group with $G_X := \beta(X, X)$ and dm as in (3).

β Calculus. Let $\beta(H, T)$ be

ω	h_1	h_2	\dots	$h_j \in H, t_i \in T$, and ω and the α_{ij} are Laurent polynomials in variables T_i , in bijection with the t_i 's
t_1	α_{11}	α_{12}	\cdot	
t_2	α_{21}	α_{22}	\cdot	
\vdots	\cdot	\cdot	\cdot	

with operations $tm_z^{xy} : \begin{matrix} \omega & \dots \\ t_x & \alpha \\ t_y & \beta \\ \vdots & \gamma \end{matrix} \mapsto \begin{matrix} \omega & \dots \\ t_z & \alpha + \beta \\ \vdots & \gamma \end{matrix}$,

$hm_z^{xy} : \begin{matrix} \omega & h_x & h_y & \dots \\ \vdots & \alpha & \beta & \gamma \end{matrix} \mapsto \begin{matrix} \omega & & h_z & \dots \\ \vdots & \alpha + \beta + \langle \alpha \rangle \beta & \gamma \end{matrix}$,

$sw_z^{th} : \begin{matrix} \omega & h_y & \dots \\ t_x & \alpha & \beta \\ \vdots & \gamma & \delta \end{matrix} \mapsto \begin{matrix} \omega \epsilon & & h_y & \dots \\ t_x & \alpha(1 + \langle \gamma \rangle / \epsilon) & \beta(1 + \langle \gamma \rangle / \epsilon) \\ \vdots & \gamma / \epsilon & \delta - \gamma \beta / \epsilon \end{matrix}$,

where $\epsilon := 1 + \alpha$, $\langle \alpha \rangle := \sum_i \alpha_i$, and $\langle \gamma \rangle := \sum_{i \neq x} \gamma_i$, and let

$R_{xy}^p := \begin{matrix} 1 & h_x & h_y \\ t_x & 0 & T_x - 1 \\ t_y & 0 & 0 \end{matrix}$	$R_{xy}^m := \begin{matrix} 1 & h_x & h_y \\ t_x & 0 & T_x^{-1} - 1 \\ t_y & 0 & 0 \end{matrix}$
---	--

Theorem. Z^β is a tangle invariant (and much more). Restricted to knots, the ω part is the Alexander polynomial. Restricted to links, it contains the multivariable Alexander polynomial. Restricted to braids, it is equivalent to the Burau representation.

Why happy? Besides applications to w-knots, everything that I know about the Alexander polynomial can be expressed cleanly in this language (even if w/o proof), except HF but including genus, ribbonness, cabling, v-knots, knotted graphs, etc., and there's potential for vast generalizations.

Idea. Given a group G and two pairs $R^\pm = (g_o^\pm, g_u^\pm) \in G^2$, map them to tings and “multiply along”, so that

This Fails! R2 implies that $g_o^\pm g_u^\mp = e$ and then R3 implies that g_o^+ and g_u^+ commute, to teh result is a simple counting invariant.

A Group Computer. Given G , can store group elements and perform operations on them:

(Also has S_x for inversion, e_x for unit insertion, d_x for register deletion, Δ_{xy}^z for element cloning, and $(D_1, D_2) \mapsto D_1 \cup D_2$ for merging, and very many obvious composition axioms relating these.

A Meta-Group. Is a similar “computer”, only its internal structure is unknown to us. Namely it is a collection of sets $\{G_X\}$ indexed by all finite sets X , and a collection of operations $m_z^{xy}, S_x, e_x, d_x, \Delta_{xy}^z$, and \cup , satisfying the exact same properties.

Example 1. The non-meta example, $G_X := G^X$.

Example 2. $G_X := M_{X \times X}(\mathbb{Z})$, with simultaneous row and column operations.

global dm \rightarrow gm

global dm → gm
