tex

We start by loading the package `\verb$KnotTheory`$` --- it is only needed because it has many specific knots pre-defined:

pdf

```
In[ ]:= << KnotTheory`
```

pdf

Loading KnotTheory` version of October 29, 2024, 10:29:52.1301.
Read more at <http://katlas.org/wiki/KnotTheory>.

tex

Next we quietly define the commands `\verb$Rot$`, used to compute rotation numbers, and `\verb$PolyPlot$`, used to plot polynomials as bar codes and as hexagonal QR codes. Neither is a part of the core of the computation of Θ , so neither is shown; yet we do show some usage examples.

pdf

```

We urge the reader to reflect on how the “QR Code” part of the above picture corresponds to the 2-variable polynomial $T_1 + 2T_2 - 4T_1^{-1}T_2^{-1}$.

Next, we decree that $T_3 = T_1 T_2$ and define the three “Feynman Diagram” polynomials F_1 , F_2 , and F_3 (those definitions are printed in a smaller font because they are equal to what was already printed in [\eqref{eq:F1}](#)–[\eqref{eq:F3}](#)):

tex

Next comes the main program computing Θ . Fortunately, it matches perfectly with the mathematical description in Section~\ref{sec:Formulas}. In line 01 we let XX be the list of crossings in an input knot KK , and φ the list of its rotation numbers, using the external program `\verb$Rot$` which we have already mentioned. We also let n be the length of XX , namely, the number of crossings in KK . In line 02 we let the starting value of AA be the identity matrix, and then in line 03, for each crossing in XX we add to AA a 2×2 block, in rows i and j and columns $i+1$ and $j+1$, as explain in Equation~\eqref{eq:A}. In line 04 we compute the normalized Alexander polynomial Δ as in~\eqref{eq:Delta}. In line 05 we let GG be the inverse of AA . In line 06 we declare what it means to evaluate, `\verb$ev$`, a formula $\text{\code{\cal e}}$ that may contain symbols of the form $g_{\nu\alpha\beta}$: each such symbol is to be replaced by the entry in position α, β of GG , but with T replaced with T_{ν} . In line 07 we start computing θ by computing the first summand in~\eqref{eq:Main}, which in itself, is a sum over the crossings of the knot. In line 08 we add to θ the double sum corresponding to the second term in~\eqref{eq:Main}, and in line 09, we add the third summand of~\eqref{eq:Main}. Finally, line 10 outputs a pair: Δ , and the re-normalized version of θ .

Next are the Conway knot 11_{n34} and the Kinoshita-Terasaka knot 11_{n42} . The two are

mutants and famously hard to separate: they both have $\Delta=1$ (as evidenced by their one-bar bar codes below), and they have the same HOMFLY-PT polynomial and Khovanov homology. Yet their Θ invariants are different. Note that the genus of the Conway knot is 3, while the genus of the Kinoshita-Terasaka knot is 2. This agrees with the apparent higher complexity of the QR code of the Conway polynomial, and with the observations in Section~\ref{sec:SandM}.

Proof of R3

```
exec
```

```
nb2tex$TeXFileName = "Invariance-R3.tex";
```

```
tex
```

First, we implement the Kronecker δ -function, the g -rules for a crossing (s,i,j) , and the g -rules for a list of crossings X :

```
pdf
```

```
In[ ]:=  $\delta_{i,j} := \text{If}[i == j, 1, 0];$ 
gRules[{s_Integer, i_, j_}] := {
   $g_{v,j\beta} \mapsto g_{vj\beta} + \delta_{j\beta},$   $g_{v,i\beta} \mapsto T_v^s g_{vi\beta} + (1 - T_v^s) g_{vj\beta} + \delta_{i\beta},$ 
   $g_{v,\alpha i^*} \mapsto T_v^s g_{v\alpha i} + \delta_{\alpha i^*},$   $g_{v,\alpha j^*} \mapsto g_{v\alpha j} + (1 - T_v^s) g_{v\alpha i} + \delta_{\alpha j^*}$ 
};
gRules[{X___List}] := Union @@ Table[gRules[c], {c, {X}}]
```

```
tex
```

We then let $\text{verb}X$ be the three crossings in the left-hand-side of the R3 move, as in Figure~\ref{fig:R3}, we let $\text{verb}A$ be the A^1 term of~\eqref{eq:ABC}, and we let $\text{verb}l$ be the result of

applying the g -rules for the crossings in $\backslash\text{verb}\$Xl\$$ to $\backslash\text{verb}\$Al\$$. We print only a ``\verb$Short$` version of $\backslash\text{verb}\$lhs\$$ because the full thing would cover about 2.5 pages:

pdf

```
In[*]:= Xl = {{1, j, k}, {1, i, k^+}, {1, i^+, j^+}};
Al = Sum[F1[c], {c, Xl}] + Sum[F2[c0, c1], {c0, Xl}, {c1, Xl}];
lhs = Simplify[Al /. gRules[Xl]];
Short[lhs, 5]
```

Out[*]//Short=

pdf

$$-\frac{1}{2(1-T_2)}(3-3T_2+\ll 128 \gg +2(1-T_2)T_2g_{2,(k^+)^+,i}(1+(1-T_1T_2)g_{3,(k^+)^+,j}+g_{3,(k^+)^+,k})+2(1-T_2)(1+T_2(T_2g_{2,(i^+)^+,i}-(-1+T_2)g_{2,(j^+)^+,i})-(-1+T_2)g_{2,(k^+)^+,i})(1+(1-T_1T_2)g_{3,(k^+)^+,j}+g_{3,(k^+)^+,k}))$$

tex

We do the same for $\$A^r\$$, except this time, without printing at all:

pdf

```
In[*]:= Xr = {{1, i, j}, {1, i^+, k}, {1, j^+, k^+}};
Ar = Sum[F1[c], {c, Xr}] + Sum[F2[c0, c1], {c0, Xr}, {c1, Xr}];
rhs = Simplify[Ar /. gRules[Xr]];
```

tex

We then compare $\backslash\text{verb}\$lhs\$$ with $\backslash\text{verb}\$rhs\$$. The output, $\backslash\text{verb}\$True\$$, tells us that we have proven~\eqref{eq:R3A}:

pdf

```
In[*]:= Simplify[lhs == rhs]
```

Out[*]=

pdf

True

tex

We show that $\$B^l=B^r\$$ by following exactly the same procedure. Note that we ignore the summation over $\$c_y\$$ and instead treat it as fixed. If an equality is proven for every fixed $\$c_y\$$, it is of course also proven for the sum over $\$c_y\$ in Y . Note also that we repeat the test twice, for the two choices of the sign of $\$c_y\$$:

pdf

```
In[*]:= Table[
  cy = {s, m, n};
  lhs = Sum[F2[c0, cy], {c0, Xl}] /. gRules[Xl];
  rhs = Sum[F2[c0, cy], {c0, Xr}] /. gRules[Xr];
  Simplify[lhs == rhs],
  {s, {1, -1}}
]
```

Out[*]=

pdf

{True, True}

tex

Similarly we prove that $\$C^l=C^r\$$, and this concludes the proof of Proposition~\ref{prop:R3}.

pdf

```
In[ ]:= Table[
  cy = {s, m, n};
  lhs = Sum[F2[cy, c1], {c1, X1}] /. gRules[X1];
  rhs = Sum[F2[cy, c1], {c1, Xr}] /. gRules[Xr];
  Simplify[lhs == rhs],
  {s, {1, -1}}
]
```

Out[]:=

pdf

```
{True, True}
```

tex

```
\\qed
```

`\begin{remark} \label{rem:E}` The computations above were carried out for generic $g_{\nu\alpha\beta}$ and for a generic $c_y=(s,m,n)$; namely, without specifying the knot diagrams in full, and hence without assigning specific values to $g_{\nu\alpha\beta}$, and without specifying m and n . Under these conditions the three parts of `\eqref{eq:ABC}` cannot mix (namely, terms from, say, A^h cannot cancel terms in B^h or C^h), and so it would have been enough to show that $E^l=E^r$, where E^h combines A^h and B^h and C^h (and a few harmless further terms) by adding c_y to the summation corresponding to A^h :

```
\[
E^h = \sum_{c \in \{c^h_{1,2,3,y}\}} F^h_1(c)
      + \sum_{c_0, c_1 \in \{c^h_{1,2,3,y}\}} F^h_2(c_0, c_1).
\]
```

But that's a simpler computation:

pdf

```
In[ ]:= ESum[X_] := (Sum[F1[c], {c, X}] + Sum[F2[c0, c1], {c0, X}, {c1, X}]) /. gRules[X];
```

pdf

```
In[ ]:= X1 = {{1, j, k}, {1, i, k+}, {1, i+, j+}};
Xr = {{1, i, j}, {1, i+, k}, {1, j+, k+}};
Table[
  Simplify[ESum[Append[X1, {s, m, n}]] == ESum[Append[Xr, {s, m, n}]]],
  {s, {1, -1}}
]
```

Out[]:=

pdf

```
{True, True}
```

tex

```
\end{remark}
```
